Validation of Prediction Uncertainty in Computational

- Uncertainty estimation in computational chemistry
- 2 Prediction uncertainty validation framework
- 3 Examples from the CC literature

CC-UQ validation practices

• Qualitative appreciation of conformity between PU and errors amplitude

- visual check of normality of z-scores histogram¹
- visual estimation of local coverage of 95% prediction interval (PI)²

Statistical estimation

- coverage of 95% prediction intervals³
- correlation of uncertainty and absolute errors⁴
- calibration/sharpness (for CC-applied ML methods)⁵

We need a consistent and shared validation framework !

Introduction

Uncertainty vs error⁶

In order to estimate a measurement uncertainty it is assumed that the result of a measurement has been corrected for all recognized significant systematic effects and that every effort has been made to identify such effects.

systematic error

component of measurement error that remains constant or varies in a predictable manner

random error

component of measurement error that varies in an **unpredictable** manner

uncertainty

non-negative parameter characterizing the **dispersion** of the quantity values being attributed to a measurand

 often estimated by a standard deviation u_{i} or the half-width of a probability interval U_p

⁶Guide to the expression of uncertainty in measurement (GUM), JCGM 100:2008, International Vocabulary of Metrology (VIM), JCGM 200:2012

Error sources in Computational Chemistry⁹

Numerical errors

- finite arithmetics, stochastic algorithms...
- mostly random errors; assumed to be well controlled⁷. except for numerical chaos⁸

Parametric uncertainty

- semi-empirical methods, statistical corrections...
- random errors: decrease with size of calibration set

Model errors

- level-of-theory errors (density functional approximation, correlation level, force-field expression...), representation errors (basis-sets, grids)...
- mostly systematic errors; often the dominant error source; no reason to be normally distributed

CC-UQ outputs

• Prediction distributions or representative samples

- available for some methods (Stochastic methods, Statistical models, Bayesian Ensembles...)
- Most UQ studies in the CC literature provide statistical summaries:
 - expanded uncertainties $(U_p, \text{ typically for } p = 0.95)^{10}$
 - standard uncertainties (u)

Note: no prediction interval without distribution hypothesis

¹⁰Ruscic (2014) Int. J. Quantum Chem. 114:1097

Validation data sets

Let us consider a typical validation set

- V_i : predicted value at point $i \in 1: M$
- u_{V_i} : uncertainty on V_i (model uncertainty)
- R_i : reference value
- u_{R_i} : uncertainty on R_i (*data* uncertainty)

Validation is based on

- $E_i = R_i V_i$: error / prediction error
- for standard uncertainties $u_{E_i} = \sqrt{u_{V_i}^2 + u_{R_i}^2}$ (prediction uncertainty)

Prediction uncertainty quantifies the dispersion of pred. errors

Pascal PERNOT (ICP)

Visual appreciation

Do the errors scale with uncertainty ?

if u_E ≠ c^{te}, plot E vs u_E and guiding lines y = k * x
if u_E = c^{te}, plot E/u_E (z-score) vs V and guiding lines y = k
as helper, plot running quantiles (Cl₉₅)

The Calibration/Sharpness framework¹²

Calibration a method is considered to be *calibrated* if the confidence of predictions matches the probability of being correct for all confidence levels

Sharpness the concentration of a predictive distribution in absolute terms. Conditional to calibration

Pb: sharpness is a property of the forecast alone and does not involve the observations.

 \longrightarrow useful in benchmarking, not in validation. . .

Tightness¹¹ a method is considered to be *tight* if it is calibrated for any relevant subgroup of the validation data (small-scale calibration)

¹¹Pernot (2022) (https://arxiv.org/abs/2204.13477)

¹²Gneiting et al. (2007) Stat. Meth. B (https://tinyurl.com/2p8nr3ab)

Limits of average calibration

- Average calibration does not guarantee tightness
 - in benchmarking, sharpness is used to select tighter forecasts
- Stronger calibration modes have been introduced:
 - group calibration¹³ where calibration is assessed on relevant subgroups of the validation dataset
 - *adversarial* group calibration¹⁴ where calibration is assessed on any random group of useful size
 - perfect calibration¹⁵
 - I propose to use **local** calibration, a variant of group calibration, where the validation set is split into contiguous areas of a chosen coordinate (predicted value, prediction uncertainty...)

 ¹³Chung *et al.* (2021) arXiv:2109.10254; Hébert-Johnson (2017) arXiv:1711.08513
 ¹⁴Zhao (2020) arXiv:2006.10288

¹⁵Levi *et al.* (2020) (http://arxiv.org/abs/1905.11659)

Different validation approaches¹⁸

• Interval-based ¹⁶

$$\lim_{M \to \infty} \frac{1}{M} \sum_{i=1}^{M} \mathbf{1} \left(E_i \in I_{E_i, p} \right) = p, \, \forall \, p \in [0, 1]$$

where $I_{E_i,p}$ is a prediction interval at probability level p

• Variance-based ¹⁷

$$\operatorname{Var}\left(E|u_E^2=\sigma^2\right)=\sigma^2,\,\forall\sigma^2$$

which does not operate at the same level as interval-based validation

• Note: ranking-based methods (correlation between u_E and |E|; confidence curves) cannot validate calibration/tightness, but can invalidate tightness...

¹⁶Kuleshov *et al.* (2018) (http://arxiv.org/abs/1807.00263)

¹⁷Levi *et al.* (2020) (http://arxiv.org/abs/1905.11659)

¹⁸Scalia et al. (2020) J. Chem. Inf. Model. (https://tinyurl.com/yc7rn7dp), Pernot (2022) _J. Chem.

Interval-based validation

An expanded uncertainty is the half-width of a prediction interval

 $I_{E_i,p} = \left[-U_{E_i,p}, U_{E_i,p}\right]$

To validate $U_{E,p}$, one should therefore test

$$p \stackrel{?}{\in} I_{95}(\nu_p, M), \text{ where } \nu_p = \frac{1}{M} \sum_{i=1}^M \mathbf{1} \left(|E_i| \le U_{p,i} \right)$$

and ν_p is a PICP (Prediction Interval Coverage Probability)

• $I_{95}(\nu_p, M)$ (Binomial Proportion CI) is estimated by a method avoiding normality hypothesis (Clopper-Pearson, cc-Wilson, Agresti-Coull...)¹⁹

¹⁹Vollset (1993) *Stat. Med.* (https://tinyurl.com/5dps8u3h)

Variance-based validation

Let us consider unbiased errors of unknown distribution

 $\mathbf{E}(E_i) = 0; \ \operatorname{Var}(E_i) = u_{E_i}^2$

Then for z-scores $z_i = E_i/u_{E_i}$ one has

 $\mathbf{E}(z_i) = 0; \ \operatorname{Var}(z_i) = 1$

and for a set of z-scores $Z = \{z_i\}_{i=1}^M$

E(Z) = 0; Var(Z) = 1

To validate Var(Z), one should therefore test

 $1 \stackrel{?}{\in} I_{95}\left(\operatorname{Var}(Z), M\right)$

• $I_{95}(\operatorname{Var}(Z), M)$ is estimated by an adapted bootstrap method $(\operatorname{BC}_a, \operatorname{ABC}_{\ldots})^{20}$ to avoid the normality-based textbook method

Pascal PERNOT (ICP)

Validation of Prediction Uncertainty in Computational

How to test tightness?

- **Proposed approach**: interpret tightness as **local calibration** and use calibration tests on subsets of the validation set wrt V or uE (or any other relevant property)
 - LCP analysis: local PICP estimation and test
 - LZV analysis: local z-scores variance testing
- **Pb**: partitioning reduces sample size (bad for test power) \rightarrow use overlapping/sliding areas for small datasets. Trends in LCP-LZV curves help diagnostic.
- Link of LZV/uE with *perfect* calibration (reliability diagram, RD)²¹

$$\operatorname{Var}\left(E|u_E^2=\sigma^2\right)=\sigma^2,\,\forall\sigma^2$$

but RD does not deal with homoscedastic datasets.

ZPE by the ATOMIC-2 composite method²⁵ iC_{P} iC_{P

A-posteriori estimation of U_{95} based on a correlation of errors with the fraction of heteroatoms in a molecule.

- Small test dataset: M = 99 $\{V_i, R_i, U_{95, V_i}\}$
- Reference data: CCSD(T) (no uncertainty)
- Authors validate by visual appreciation of error bars

 25 Bakowies and von Lilienfeld (2021) JCTC (https://tinyurl.com/ms3dy7yv), Pernot (2022) J Chem Phys (https://doi.org/10.1063/5.0084302)

Pascal PERNOT (ICP)

Examples from the CC literature

ZPE by the ATOMIC composite method

PICP testing at p = 0.95

- $\nu_{0.95} = 0.92(3)$: average calibration is OK
- large uncertainty on PICPs, but the trends are informative ۲
- from the LCP analysis, one sees a systematic bias: ۲ small PUs are underestimated, large ones are overestimated

Pascal PERNOT (ICP)

Pascal PERNOT (ICP) Validation of Prediction Uncertainty in Computational

Formation heats by the mBEEF method²⁶

- Bayesian Ensembles method inflates *parametric uncertainty* of exchange-correlation model to cover errors amplitude
 - strong functional constraints: tightness ???
 - does not disambiguate model uncertainty from reference data uncertainty
- Set of $M = 257 \{V_i, R_i, u_{V_i}\}$
- R_i experimental, no uncertainty provided

²⁶Pandey and Jacobsen (2015) Phys. Rev. B (https://tinyurl.com/5dv9spnn), Pernot (2017) J. Chem. Phys. (https://tinyurl.com/yb6uzwzr), Pernot and Cailliez (2017) AIChE J. (https://tinyurl.com/2xxcfs2f)

Examples from the CC literature

Formation heats by the mBEEF method

- Var(Z) = 1.3(2), average calibration OK
- the LZV analysis shows that small PUs are underestimated, while large ones are overestimated
- the confidence curve is catastrophic ۲
- these uncertainties should not be trusted

Query by Commitee UQ

QbC uncertainties (n = 8) on formation enthalpies for AlQM1 and ANI-1ccx²⁷. Set of $M = 472 \{E_i, u_{V_i}\}$

²⁷Zheng et al. (2022) J. Phys. Chem. Lett. (https://tinyurl.com/ccefk79z)

Pascal PERNOT (ICP)

Validation of Prediction Uncertainty in Computational

Query by Commitee UQ

- QbC does not provide a prediction uncertainty
- but both methods point reliably to largest errors (good for active learning !)

Pascal PERNOT (ICP)

Bayesian Neural Network

Data issued from a BNN trained to predict a MD potential²⁸ (M = 5923)

• The color scale for uncertainty is not a proper tool for validation

 Validation of Prediction Uncertainty in Computational
 CECAM (2022-06-22)
 25/28

ICP COTS UNIVERSITE

Bayesian Neural Network

• This BNN uncertainty is NOT a prediction uncertainty (Var(Z) = 30) and should not be used for active learning...

Calibration is easy, tightness is tough !

- Calibration/Tightness : a principled framework for UQ validation
- CC-adapted C/T validation methods
 - standard PU : test z-scores variance (LZV analysis), or build RD
 - expanded PU : test PICP values (LCP/LRR analysis)

• CC-UQ methods rarely reach calibration and/or tightness

- datasets often too small for solid conclusions
- should we loosen the validation criteria ?
- how-much mis-calibration/mis-tightness is acceptable for a given application ? (e.g. calibration is not useful for active learning...)

Warmful thanks to...
